

Storm Damage Across the United States

This poster explores how severe storm events impact the United States through frequency, seasonality, human consequences, and economic damage. Using NOAA’s Storm Events dataset, the analysis answers three key questions: Which storm types occur most often and cause the most harm? How do storm types vary by season? And which states experience the highest economic losses? Together, these insights reveal clear patterns in storm behavior and regional vulnerability.

Storm Types Causing the Most Harm

Frequent storm types like Thunderstorm Wind and Hail dominate nationally, while Tornadoes and extreme heat events cause the highest number of injuries. This section highlights which storms occur most often and which pose the greatest risk to people.

Seasonality of Storm Events

Storm activity peaks in late spring and summer, with different storm types showing distinct seasonal patterns. Thunderstorms and hail intensify during warm months, while winter storms occur primarily early in the year.

State-Level Impact

Storm Damage Across the United States

Storm damage is heavily concentrated in a few states, with Texas, California, and Florida experiencing the largest economic losses. This map illustrates where severe weather has the greatest financial impact across the country.

KEY TAKEAWAYS:

The analysis reveals clear patterns in how storms impact the United States. Thunderstorm Wind, Hail, and Flash Floods occur most frequently, while Tornadoes and extreme heat-related events cause the greatest number of injuries.

Storm activity peaks from late spring through mid-summer, especially in May, June, and July, when severe weather conditions are most likely to develop. The seasonality heatmap further shows that different storm types dominate at different times of the year for example, hail and thunderstorms intensify in spring and summer, while winter storms occur primarily in the colder months.

At the state level, the financial burden of storm damage is highly uneven, with states such as Texas, California, and Florida experiencing disproportionately high economic losses. Together, these findings highlight how storm frequency, timing, and geography combine to shape the overall impact of severe weather across the United States.
